# Classification Algorithms: Bagging

### Bagging

#### Bagging (or Bootstrap aggregating)

#### Create different bootstrap data sets

- 1. Let D denote the original data set of N samples,  $\mathcal{Y}$  denote the label set and let k denote the number of bootstrap data sets.
- 2. For j = 1, 2, ... k do:
  - 2.1. Create a data set  $D_i$  of size N by sampling uniformly at random with replacement from D.
  - 2.2. Build a base classifier  $C_i$  using  $D_i$ .
- 3. Inference for test sample  $\hat{x}$  is done as:  $\hat{y} = rg \max_{y \in \mathcal{Y}} \sum_{i=1}^k \mathbb{I}(C_j(\hat{x}) == y)$

Each sample has a probability of  $1-(1-1/N)^N$  of getting selected in each data set  $D_j$ . For large N, this quantity can be approximated as  $1 - 1/e \approx 0.632$ 

Thus on an average each bootstrap data set  $D_i$  has 63% of samples in the original data set D.

# Classification Algorithms: Boosting

## Boosting: AdaBoost

#### Algorithm AdaBoost

Input: sequence of N labeled examples  $\langle (x_1, y_1), \dots, (x_N, y_N) \rangle$ distribution D over the N examples weak learning algorithm WeakLearn integer T specifying number of iterations

Initialize the weight vector:  $w_i^1 = D(i)$  for i = 1, ..., N. Do for t = 1, 2, ..., T

1. Set

$$\mathbf{p}^t = \frac{\mathbf{w}^t}{\sum_{i=1}^N w_i^t}$$

- 2. Call **WeakLearn**, providing it with the distribution  $\mathbf{p}^t$ ; get back a hypothesis  $h_t: X \to [0,1]$ .
- 3. Calculate the error of  $h_t$ :  $\epsilon_t = \sum_{i=1}^N p_i^t |h_t(x_i) y_i|$ .
- 4. Set  $\beta_t = \epsilon_t/(1 \epsilon_t)$ .
- 5. Set the new weights vector to be

$$w_i^{t+1} = w_i^t \beta_t^{1-|h_t(x_i)-y_i|}$$

Output the hypothesis

$$h_f(x) = \begin{cases} 1 & \text{if } \sum_{t=1}^T \left(\log \frac{1}{\beta_t}\right) h_t(x) \ge \frac{1}{2} \sum_{t=1}^T \log \frac{1}{\beta_t} \\ 0 & \text{otherwise} \end{cases}.$$

## AdaBoost - a loss perspective<sup>†</sup>

- Input: N samples  $\{(x^i, y^i)\}_{i=1}^N$ ,  $x^i \in \mathbb{R}^d$ ,  $y^i \in \{+1, -1\}, \forall i \in \{1, 2, ..., N\}$ .
- Initialize weights  $w_i^1 = 1/N, \forall i \in \{1, 2, ..., N\}.$
- For t = 1, 2, ..., T do:
  - ▶ Train a weak classifier with examples weighed using current weights  $w_i^t$  by minimizing:  $\epsilon_t = \sum_{i=1}^N w_i^t \mathbb{I}(h_t(x^i) \neq y^i)$ .
  - $\qquad \qquad \textbf{Compute} \ \alpha_t = \tfrac{1}{2} \ln \tfrac{1-\epsilon_t}{\epsilon_t}$
  - Update weights as:  $w_i^{t+1} = w_i^t e^{-\alpha_t y^i h(x^i)}$
  - ► Normalize  $w_i^{t+1} = w_i^{t+1} / \sum_{i=1}^{N} w_i^{t+1}$ .
- Output: Final classifier  $h(x) = \text{sign}(\sum_{t=1}^{T} \alpha_t h_t(x))$ .

### 10 data points and 2 features

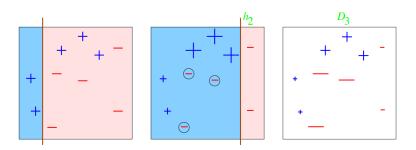

Example from Ameet Talwalkar's slides on AdaBoost

Round 1: t = 1

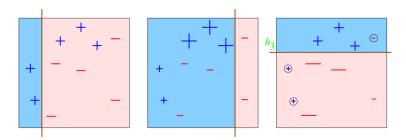

- 3 misclassified (with circles):  $\epsilon_1 = 0.3 \rightarrow \mathcal{C}_1 = 0.42$ .
- Weights recomputed; the 3 misclassified data points receive larger weights

Round 2: t=2

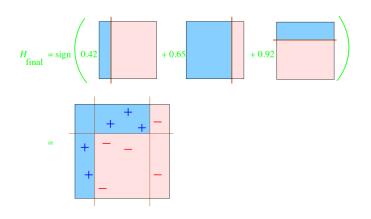

- 3 misclassified (with circles):  $\epsilon_2=0.21 \rightarrow 0.2=0.65$ . Note that  $\epsilon_2\neq 0.3$  as those 3 data points have weights less than 1/10
- 3 misclassified data points get larger weights
- Data points classified correctly in both rounds have small weights

Round 3: t = 3

- 3 misclassified (with circles):  $\epsilon_3 = 0.14 \rightarrow 0_3 = 0.92$ .
- Previously correctly classified data points are now misclassified, hence our error is low: what's the intuition?
  - Since they have been consistently classified correctly, this round's mistake will hopefully not have a huge impact on the overall prediction

### Final classifier: combining 3 classifiers

• All data points are now classified correctly!
